

Carnegie Institution of Washington publication Volume 179

This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1913 Excerpt: ... writer must confess that he is unable to draw a clear line between sables and sooty yellows in all cases. The term sooty yellow is therefore intended in this paper to cover both varieties. It is possible to explain the appearance of sooty yellows on the basis of fluctuation in activity of the factor R, restriction. Thus, when R is present in full strength the animal is clear yellow; if R is slightly weaker, some dark pigment shows itself. The amount of dark pigment visible becomes progressively greater as the factor R becomes weaker or takes on a rhythmical activity. Thus, if R is hampered in activity during the growth of the first part of the hair, we have a dark tip formed. But if R comes into full activity again, a yellow band results, followed by a second weakening of R, resulting in a dark base to the hair. This would account for the superficial similarity to the agouti pattern. Reversed sables may possibly result from a reversal of the order in which the strong and weak periods of R occur. So, too, those very dark sooty yellows that lack the ticked-hair pattern may be considered due to continued weakness of the factor R during development of the hair of the first coat. When the second coat is formed, however, the factor R makes its appearance felt more strongly and an ordinary type of sable results, with less dark pigment than was present on the first coat. In all such cases the idea is present that there is quantitative variation in the activity of the restriction factor R, showing itself in the varying amount of black or dark pigment present. If such weakness is due to any interchange of substance between gametes or any quantitative inexactitude in the process of segregation, we should expect
